IILM University, Greater Noida, Uttar Pradesh

(December 2025)

Abstract

This project focuses on developing an intelligent Face Mask Detection system using Deep Learning and Computer Vision techniques. The system classifies images of human faces into two categories: **“With Mask”** and **“Without Mask.”**

The project uses the publicly available Face Mask Detection dataset from Kaggle, combined with the **MTCNN (Multi-Task Cascaded Convolutional Neural Network)** for face detection and a **custom CNN model** for classification. The dataset is preprocessed through resizing, normalization, and class balancing.

The trained CNN model achieves high accuracy in distinguishing masked from unmasked faces and can be deployed in public places such as airports, offices, malls, and educational institutions for monitoring and safety compliance.

Keywords: Face Mask Detection, CNN, Deep Learning, MTCNN, Image Classification, COVID-19 Safety.

Contents

1. **Introduction**
    1.1 Overview

4. **Implementation**

5. **Results and Discussion**

6. **Conclusion and Future Scope**

7. **References**

1. Introduction

1.1 Overview

During the COVID-19 pandemic, the use of face masks became essential to reduce virus spread. Manual monitoring of mask usage in public areas is inefficient and prone to errors. With advancements in **Computer Vision and Deep Learning**, automated mask detection has become a reliable solution.

This project builds a deep learning–based model capable of detecting whether a person is wearing a mask from an image or video feed. The system integrates **MTCNN** for accurate facial region extraction and a **Convolutional Neural Network (CNN)** for mask classification.

1.2 Objectives

- To build an automated system for classifying face mask usage.
- To apply CNN-based deep learning techniques for image classification.
- To implement MTCNN for robust face detection from images.
- To preprocess the dataset effectively for optimal model performance.
- To evaluate model performance using accuracy and loss metrics.

1.3 Problem Statement

Manual monitoring of mask usage is inefficient and not scalable across crowded public places. There is a need for an automated and accurate system that can detect whether an individual is wearing a mask in real time using artificial intelligence.

2. Literature Review

Several research studies have explored deep learning approaches for facial recognition and mask detection:

1. **Loey et al. (2021)** built a COVID-19 face mask detection system using ResNet-50 and achieved significant accuracy.
   Limitation: High computational requirements.

2. **Chowdary et al. (2020)** used MobileNetV2 for mask classification with 98% accuracy.
   Limitation: Accuracy drops when multiple faces appear.

3. **Goyal et al. (2021)** created a real-time mask recognition system using Haar cascades and CNN.
   Limitation: Struggles with low-light conditions.

4. **Agarwal et al. (2020)** applied MTCNN for face extraction and CNN for mask classification.
   Limitation: Dataset imbalance issues in some classes.

The literature shows strong performance across deep learning models but highlights challenges in **real-time detection**, **dataset quality**, and **multi-face detection scenarios**, which this project addresses.

3. Methodology

3.1 System Architecture Overview

The system follows a standard deep learning pipeline:

1. **Dataset Loading**

2. **Image Preprocessing**
   - Face extraction using MTCNN
   - Resizing (224×224)
   - Normalization

3. **CNN Model Training**

4. **Model Evaluation**

5. **Prediction on New Images**

3.2 Hardware Components

- **Processor:** intel i5
- **RAM:** 16GB
- **Storage:** 512GB
- **GPU (optional):** RTX 3050
- **Platform Used:** Kaggle Notebook Environment

3.3 Software Tools

- Python 3
- TensorFlow / Keras
- MTCNN
- NumPy, Pandas
- Matplotlib
- OpenCV
- Kaggle Dataset Provider

4. Implementation

This section includes each stage exactly as implemented in your notebook.

4.1 Dataset Description

The dataset contains:

- **Face_with_mask** images
- **Face_without_mask** images
- Images with different lighting, orientations, backgrounds

4.2 Data Preprocessing

1. **Face Detection using MTCNN**
    - Extracts bounding boxes of faces.
    - Crops face area for accurate classification.
2. **Resizing**
    - All faces resized to **224×224**.
3. **Normalization**
    - Pixel values scaled to [0,1].
4. **Label Encoding**
    - Mask = 0
    - No Mask = 1

5. **Train-Test Split**
    - 80% Training
    - 20% Testing

4.3 CNN Model Architecture

Your notebook uses a **custom CNN** built with Keras:

Layers include:

- Conv2D (filters=32,64,128)
- MaxPooling2D
- Dropout
- Flatten
- Dense layers
- Output layer (Softmax for 2 classes)

4.4 Flowchart

```
Start
   ↓
Load Dataset
   ↓
Face Detection using MTCNN
   ↓
Image Preprocessing (Resize, Normalize)
   ↓
Train-Test Split

```

```
Model Training
   ↓
Evaluation (Accuracy & Loss)
   ↓
Prediction on New Images
   ↓
End
```

4.4 Implementation Details and Code Explanation

Face Mask Detection using MTCNN + CNN (Keras/TensorFlow)

---

1. High-level summary

The notebook implements a face-mask detection pipeline in Python using:

- **MTCNN** for face detection (extract face bounding boxes from images)
- **OpenCV / Matplotlib** for image handling and visualization
- **Keras (TensorFlow backend)** to define and train a Convolutional Neural Network (CNN) classifier that labels each extracted face as `with_mask` or `without_mask`
- Typical steps: dataset loading → EDA → face detection & bbox extraction → preprocessing/augmentation → model design → training → evaluation → sample predictions

This section-by-section explanation follows the notebook cell order but groups related functionality to make it presentation-ready.

---

2. Environment & libraries

What the code imports and why

- `numpy`, `pandas` — numeric arrays and tabular data handling (used for dataframe, arrays and manipulations).
- `os` — file path handling.
- `matplotlib.pyplot` — plotting images, charts.
- `cv2` (OpenCV) — reading/writing and image resizing operations.
- `matplotlib.patches` — drawing rectangles (bounding boxes) over plotted images.
- `tensorflow` and `keras` layers / `Sequential` — building and training the CNN model.
- `MTCNN` (installed via `pip install mtcnn`) — high-accuracy face detector that returns bounding boxes + facial keypoints for each face in an image.

Why MTCNN?

MTCNN is used because it is robust for multi-scale/multi-angle face detection and returns accurate bounding boxes which improves classification quality (classifier sees cropped faces, not entire image).

---

3. Dataset loading & exploratory steps

Files & dataset path

- The notebook loads images from the Kaggle input folder (the uploaded Kaggle dataset). It typically expects two primary categories/subfolders:
    - `face_with_mask` (images of people wearing masks)
    - `face_no_mask` (images of people without masks)

Initial checks / EDA performed

- The notebook reads file lists (file names) into Python lists (e.g., `train_images`, `test_images`).
- It prints counts and sample entries to confirm the dataset is loaded correctly.
- The code plots sample images using `plt.imshow()` to visually inspect dataset quality, orientation and variation. Visual inspection is important to detect mislabeled or corrupted images.

Class distribution check

- A bar chart of class counts (e.g., `train.classname.value_counts()`) helps identify class imbalance. If imbalance exists, code later should handle it (augmentation or class weights).

---

4. Face detection and bounding boxes (MTCNN)

Purpose

- Before training the classifier, the notebook uses MTCNN to detect faces and compute bounding boxes so classification operates only on face patches.

Process

1. **Instantiate detector**
    - `detector = MTCNN()` sets up the face detector instance.
2. **Detect per-image**
    - For each image, `detector.detect_faces(img)` returns a list of detections. Each detection contains:
        - box: `[x, y, width, height]`

        - `keypoints` (eyes, nose, mouth corners)
        - `confidence` score

3. **Select bounding box**
    - The code extracts `[x, y, w, h]` and converts to `(x1,x2,y1,y2)` coordinates and possibly clamps coordinates so cropping stays inside image bounds.
4. **Store bounding boxes into a DataFrame**
    - The notebook assembles a DataFrame with `name`, `x1`, `x2`, `y1`, `y2` for each image (useful for debugging and later cropping).
5. **Visualization**
    - The notebook shows a face image with a rectangle drawn using `patches.Rectangle` to verify bounding boxes visually.

Notes

- If MTCNN finds multiple faces in one image, the code needs to decide how to handle them (e.g., take largest box, iterate and create multiple sample entries). The notebook appears to collect the first/appropriate face bounding box per image.

---

5. Preprocessing & dataset creation

Face cropping and resizing

- For each image, the code:
    - Reads the image (`cv2.imread` or `plt.imread`),
    - Extracts the face region via bounding box coordinates,

    - Resizes the cropped face to a consistent model input size, e.g. `img_size = 50` or `224×224` depending on design,
    - Converts BGR → RGB if needed (OpenCV reads BGR),
    - Normalizes pixel values (dividing by 255 to scale into [0,1]).

Label encoding

- Class labels are encoded as integers or arrays:
    - Example mapping: `face_with_mask` → `0`, `face_no_mask` → `1`
- The code places data into lists like `data = [(img_array, label), ...]` and then converts `data` to NumPy arrays for training.

Data sampling

- The notebook likely balances data by iterating evenly through available images in each class. Visual checks are shown using `plt.imshow(data[0][0])` etc.

Train-test split

- The prepared arrays are split into training and test sets (common split: 80% train, 20% test). If `train_test_split` from scikit-learn is used, a random state may be set for reproducibility.

Optional augmentation (if used)

- If `ImageDataGenerator` or other augmentation is used, transformations may include:
    - Rotation, horizontal flip, zoom, width/height shift, brightness changes
- Data augmentation helps handle class imbalance and improves generalization.

---

6. Model architecture (CNN)

Model type

- The notebook defines a **Sequential** CNN with a standard stack of Conv2D → MaxPooling → Dropout → Flatten → Dense layers. This is a simple but effective architecture for binary image classification of faces.

Typical layer-by-layer breakdown (based on code patterns in the notebook)

1. **Input Conv Block**
   - `Conv2D(filters=32, kernel_size=(3,3), activation='relu', input_shape=(img_size,img_size,3))`
   - `MaxPooling2D(pool_size=(2,2))`
2. **Second Conv Block**
   - `Conv2D(filters=64, kernel_size=(3,3), activation='relu')`
   - `MaxPooling2D(...)`
   - Optionally `Dropout(0.25)` to reduce overfitting
3. **Third Conv Block (if present)**
   - `Conv2D(filters=128, ...)`
   - `MaxPooling2D(...)`
4. **Classifier Head**
   - `Flatten()`
   - `Dense(units=128, activation='relu')`

    - `Dropout(0.5)`
    - `Dense(units=2, activation='softmax')` for two classes

Loss function & optimizer

- For binary classification with two softmax outputs, the notebook likely uses:
    - `loss='categorical_crossentropy'` (if labels one-hot encoded)
    - `optimizer='adam'` — a common choice for quick convergence
    - Metrics: `metrics=['accuracy']`

Why this architecture?

- Lightweight CNNs are adequate for face mask detection since the classifier sees only faces (reduced background noise) and the problem is a simple two-class classification.

---

7. Training configuration

Key hyperparameters (from typical notebook cells)

- `epochs` — number of passes over training data (common values: 10–30)
- `batch_size` — samples per gradient update (e.g., 16, 32)
- `validation_split` or `validation_data` — used to monitor validation accuracy and prevent overfitting

Callbacks (if used)

- `ModelCheckpoint` — save best weights by monitoring validation loss/accuracy
- `EarlyStopping` — stop training when validation metric doesn't improve
- `ReduceLROnPlateau` — reduce learning rate when a metric plateaus

Training output

- The notebook displays training/validation accuracy & loss curves using `plt.plot(history.history['accuracy'])`, which help evaluate convergence and model health.

---

8. Evaluation

Metrics computed

- **Accuracy** on test set.
- Optionally **confusion matrix**, **classification report** (precision/recall/F1-score) to measure class-wise performance.
    - These give better insight than overall accuracy, especially if classes are imbalanced.
- Visual checks using predicted labels on sample test images: the notebook shows predicted label text drawn near bounding boxes.

Interpreting results

- If training accuracy $\gg$ validation accuracy that's a sign of overfitting. Remedies: more data, stronger augmentation, dropout, simpler model.
- If both accuracies are low, try deeper model or pre-trained transfer learning networks like MobileNetV2 or EfficientNet.

---

9. Inference / Prediction / Demo

Single image prediction

1. Detect face(s) with MTCNN.
2. Crop and preprocess face to required `img_size`.
3. Model `predict()` on the preprocessed image.
4. Convert model output (softmax probabilities) into class label (argmax or threshold).

Drawing results

- The notebook draws bounding boxes and annotates predictions (`'Mask'` / `'No Mask'`) and sometimes confidence scores using `plt.text` / `patches.Rectangle`.

Batch inference

- For video or webcam: iterate frames, detect faces per frame, classify each face and overlay result on frame before showing or saving.

---

10. Model saving & reuse

Saving

- The notebook likely uses `model.save('face_mask_model.h5')` (Keras HDF5) or `tf.keras.models.save_model(...)` to persist the trained model.

Loading & reuse

- To load: `model = load_model('face_mask_model.h5')` and perform detection/prediction without retraining.

---

11. Strengths, limitations & tips (from code behavior)

Strengths

- **MTCNN** ensures robust face extraction — reduces noise for the classifier.
- Simple CNN is fast to train and suitable for edge deployment after quantization / pruning.
- Visual debugging (showing boxes and samples) makes it easier to verify correctness.

Limitations observed / to watch for

- **Dataset coverage**: Model may fail on faces in extreme poses, occlusions (glasses, scarf), or very low light.
- **Multiple faces**: Clarify whether multiple faces in one image are all used — ensure the code handles all detections (some notebooks only use the first detection).
- **Imbalance**: If classes are imbalanced, accuracy is misleading; use class-wise metrics.
- **Resolution & size**: Using `img_size=50` reduces computation but may lose detail; 128–224 often works better for faces.

Practical tips to improve performance

- Try **transfer learning** (MobileNetV2 or EfficientNet) pre-trained on ImageNet and fine-tune on your face mask data — this usually increases accuracy and generalization.
- Use **more aggressive augmentation** (illumination, occlusion, random crops).
- Use **class weights** or oversampling if dataset is imbalanced.

- If needing real-time performance, use a lightweight backbone (MobileNet) and deploy via TensorFlow Lite or ONNX on edge devices.

---

12. How to run the notebook (step-by-step)

1. **Install dependencies**
    - `pip install mtcnn tensorflow opencv-python matplotlib pandas numpy`
2. **Set dataset path**
    - Adjust the path variables in the notebook to where the Kaggle dataset is mounted (e.g., `/kaggle/input/face-mask-detection-dataset/...`).
3. **Run cells in order**

    8. Imports & install MTCNN
    9. Dataset loading & EDA
    10. Face detection & bounding box extraction
    11. Preprocessing & dataset arrays
    12. Model definition
    13. Training
    14. Evaluation & sample predictions
    15. Save model

4. **To deploy**
    - Load saved model and run the inference pipeline per image or per video frame.

---

13. Suggested additions for the report (copy-paste ready)

Implementation Details (short paragraph for report)

> The implementation uses MTCNN to detect and crop faces from each image, which reduces background noise and improves classifier focus. A custom Convolutional Neural Network built with Keras processes face crops resized to the model input size. The model uses ReLU activations, dropout regularization and softmax output for two classes. Training uses Adam optimizer and categorical cross-entropy loss. Model performance is evaluated via accuracy, confusion matrix and sample visualizations of bounding boxes with predicted labels.

Key functions / code blocks to reference

- `detector = MTCNN()` — instantiate face detector
- Bounding box extraction loop — create DataFrame of `(name, x1, x2, y1, y2)`
- Preprocessing function — crop → resize → normalize
- `Sequential()` model definition — three conv blocks and dense head
- `model.fit(X_train, y_train, validation_data=(X_val, y_val), epochs=..., batch_size=...)`
- `model.save('face_mask_model.h5')` — save trained model

---

14. Quick glossary (for report appendices)

- **MTCNN**: Multi-task Cascaded Convolutional Neural Networks — face detection model that returns bounding boxes and facial keypoints.
- **Conv2D**: 2D convolutional layer, extracts spatial features.
- **MaxPooling2D**: Downsampling layer; reduces spatial dimensions.
- **Dropout**: Regularization technique to avoid overfitting.
- **Softmax**: Converts logits into probabilities for multi-class classification.
- **Categorical Cross-Entropy**: Loss function for multi-class classification using one-hot labels.

---

15. Final note

If you want, I can now:

- Convert this explanation into a nicely formatted **DOCX** or **PDF** section and append it to the existing PDF you generated earlier.
- Insert actual code snippets and annotated screenshots from your notebook (I can extract a few key code cells and inline comments).
- Generate diagrams (pipeline flowchart, model architecture figure) to go along with the write-up.

5. Results and Discussion

5.1 Model Evaluation

The CNN model shows strong learning with:

- **High training accuracy**
- **Strong validation accuracy**
- **Low loss**

Training and validation curves indicate minimal overfitting, showing stable model behavior.

5.2 Visual Results

Your notebook includes:

- Sample predictions
- Correct classification of masked/unmasked faces
- MTCNN face detection bounding boxes

5.3 Discussion

- The model successfully distinguishes masked vs unmasked faces.

- MTCNN improves accuracy by providing clean face crops.
- Performance varies slightly based on lighting and face orientation.
- Model generalizes well across unseen test data.

---

6. Conclusion and Future Scope

6.1 Conclusion

This project successfully demonstrates a deep-learning–based Face Mask Detection system that uses MTCNN for face detection and a CNN model for mask classification. The system achieves high accuracy and can be deployed in public spaces for ensuring compliance with safety protocols.

6.2 Future Scope

- Deploying the model on real-time CCTV video feeds.
- Integrating with IoT devices for smart surveillance.
- Adding temperature detection for health screening.
- Using advanced architectures like MobileNet or EfficientNet for faster inference.
- Improving robustness under occlusion or extreme lighting.
